

Model Uncertainties and Parameter Estimation

15.5.2024 — Andreas Scheidegger

Goals of today

- i. You can identify different *sources* of model *uncertainties*.
- ii. You know how *uncertainties* can be *quantified* mathematically.
- iii. You can assess different ways to obtain *parameter values*.

Model uncertainties

What is a model?

A computer program:

A mathematical function*:

$$\mathbf{y} = m(\mathbf{x}; \boldsymbol{\theta})$$

*if the model output is stochastic, we often use capital letters: $\mathbf{Y} = M(\mathbf{x}; \boldsymbol{\theta})$

Models are wrong: sources of uncertainty

Almost all models suffer from these sources of uncertainty:

1. Input uncertainty
2. Parameter uncertainty
3. Model structure uncertainty
4. Output (measurement) uncertainty
5. (Scenario uncertainty)

Sources of Model Uncertainty

Input → Process → Response → Observation

Reality

Sources of uncertainty: Phytoplankton Model

Think about examples for each source of uncertainty:

1. Input uncertainty
2. Parameter uncertainty
3. Model structure uncertainty
4. Output (measurement) uncertainty
5. (Scenario uncertainty)

Which source do you judge the most relevant?

| Process | Substances / Organisms | | Rate |
|-----------------|------------------------------|------------------------------|--------------------|
| | HPO4 [gP/m ³] | ALG [gDM/m ³] | |
| Growth of algae | $-\alpha_{P,ALG}$ | 1 | $\rho_{gro,ALG}$ |
| Death of algae | | -1 | $\rho_{death,ALG}$ |

Descriptions of uncertainties

How can we describe uncertainties?

1. Guess tomorrow's air temperature in Zurich.
2. How (un)certain are you about your guess?

→ *Probability distributions* are a natural mathematical framework to describe uncertainties.

Probabilities, are they all the same?

i. What is the probability to throw a five with a dice?

ii. What is the probability to win the Swiss lottery?

iii. What is the probability that it snows tomorrow

iv. What is the probability that it has snowed yesterday on Uetliberg?

} *repeatable events*

} *unique events*

These are *interpretations*, the mathematical rules (probability calculus) are always the same!

Probability interpretations*

Frequentist interpretation:

- Probability describes the frequency of a random event
- Only applicable if an event can be replicated, e.g. lab experiments, dice, coin flips

Bayesian or subjective interpretation:

- Probability describes the “knowledge” or “belief” about an event
- Is *subjective* because everybody has different information
- When representing the current state of scientific knowledge, we use “intersubjective” probabilities about which multiple scientists agree.

*This is a deep, philosophical topic, see e.g. <https://plato.stanford.edu/entries/probability-interpret/>

Uncertainty Analysis

- Error propagation
- Sensitivity Analysis

Error Propagation

I know the *uncertainty of the **inputs** or **parameters***.
What is the resulting uncertainty of the ***outputs***?

Analytical Error Propagation

Given the standard deviation σ_A and σ_B , what is σ_f ?

Function (model)

Variance of output

$$f = aA \pm bB$$

$$\sigma_f^2 = a^2 \sigma_A^2 + b^2 \sigma_B^2$$

$$f = AB$$

$$\sigma_f^2 \approx (AB)^2 \left[\left(\frac{\sigma_A}{A} \right)^2 + \left(\frac{\sigma_B}{B} \right)^2 \right]$$

For full table see:

https://en.wikipedia.org/wiki/Propagation_of_uncertainty

Based on linear *approximation!*

Monte Carlo Error Propagation

```
y = empty vector

for i in 1:N
  # sample inputs from distributions
  x ~ rnorm(10, 2)      # Normal( $\mu=10$ ,  $\sigma=2$ )
   $\theta$  ~ runif(0, 2)   # Uniform(0, 2)

  # run model
  y[i] = model(x,  $\theta$ )
end

sd(y)
mean(y)
histogram(y)
```

Exact if N goes to infinity

Sensitivity Analysis

How important are the different **parameters** and/or model **inputs** for the model **output**?

Factors

(SA does not distinguish between inputs and parameters)

Parameter estimation

Where do we get the numbers from?

How do we get the parameters values?

Parameters phytoplankton model

```
# definition of model parameters:

param  <- list(k.gro.ALG   = 0.5,      # 1/d
              k.death.ALG  = 0.1,      # 1/d
              K.HPO4       = 0.002,    # gP/m3
              alpha.P.ALG  = 0.003,    # gP/gDM
              A            = 5e+006,   # m2
              h.epi       = 5,        # m
              Q.in        = 5,        # m3/s
              C.HPO4.in   = 0.04,     # gP/m3
              C.HPO4.ini  = 0.004,    # gP/m3
              C.ALG.ini   = 0.1)      # gDM/m3
```

Parameter values can be obtained by:

- I. Laboratory Experiments
- II. Scientific literature
- III. Calibration of model output to field observations

Information on parameter values

I. Laboratory Experiments

- Parameter needs a physical interpretation
- Lab conditions are not always transferable to real system

II. Scientific literature

- Measured under different conditions, varying methodologies, ...
- Only for “famous” parameters possible

III. Calibration of model output to field observations

- Result depends on the model
- May not be transferable

Model Calibration

What *parameters* make the *outputs* most similar to the observations?

Demo

Manual Calibration

Model calibration techniques

- i. Manual calibration
- ii. Minimizing a loss function
- iii. Maximum Likelihood estimation — a special loss function
- iv. Bayesian inference — combine field data with other information

Calibration with loss functions

$$\hat{\theta} = \overbrace{\arg \min_{\theta}}^{\text{take } \theta \text{ at minimum}} L \left(\overbrace{M(x, \theta)}^{\text{model output}}, \overbrace{Y_{\text{obs}}}^{\text{observations}} \right)$$

loss function

- Any loss function that appears sensible can be used
- Parameter uncertainty cannot be quantified!

Examples of loss functions

$$\Phi_{\text{SSE}}[\boldsymbol{\theta}] = \sum_{t=1}^{N_t} \left(q_t^{\text{obs}} - q_t^{\text{sim}}[\boldsymbol{\theta}] \right)^2$$

$$\Phi_{\text{RMSE}}[\boldsymbol{\theta}] = \sqrt{\frac{1}{N_t} \Phi_{\text{SSE}}[\boldsymbol{\theta}]}$$

$$\Phi_{\text{NS}}[\boldsymbol{\theta}] = 1 - \left(\frac{\Phi_{\text{RMSE}}[\boldsymbol{\theta}]}{\sigma_{\text{obs}}} \right)^2$$

$$\Phi_{\text{SAE}}[\boldsymbol{\theta}] = \sum_{t=1}^{N_t} \left| q_t^{\text{obs}} - q_t^{\text{sim}}[\boldsymbol{\theta}] \right|$$

Maximum likelihood estimation

$$\hat{\theta} = \arg \max_{\theta} \underbrace{p_M (Y_{\text{obs}} \mid x, \theta)}_{\text{Likelihood function}}$$

Likelihood function

- The likelihood function is derived from *probabilistic assumptions* about the data generating process.
- Parameter uncertainty can be approximated (see e.g. https://www.sherrytowers.com/mle_introduction.pdf, section 5)

Likelihood function

A likelihood function $p(\text{data} \mid \theta)$ answers the following question:

“Given a *stochastic* model that generates random data. If the parameters are set to θ , what is probability (density) that the randomly generated data equal the observed data?”

Note, most of our models are deterministic (i.e. non-random).
The most common approach is to assume an additional random error on the output.

Likelihood function: example of a deterministic model + noise

deterministic model

$$Y_i = \overbrace{m(x; \theta)}^{\text{deterministic model}} + \underbrace{\epsilon_i}_{\text{noise}}$$

$$\epsilon_i \sim N(0, \sigma^2)$$

Likelihood for a single observations

$$p_i(y_i | x_i, \theta, \sigma) = \text{pdf of } N(m(x_i; \theta), \sigma^2)$$

i.e. the pdf of a normal distribution with mean = $m(x; \theta)$ and standard deviation σ .

Likelihood for all observations

$$p(\mathbf{y} | \mathbf{x}, \theta, \sigma) = \prod_i p_i(y_i | x_i, \theta, \sigma)$$

Demo

Likelihood function

Parameter identifyability

$$V = h_{epi} * A$$

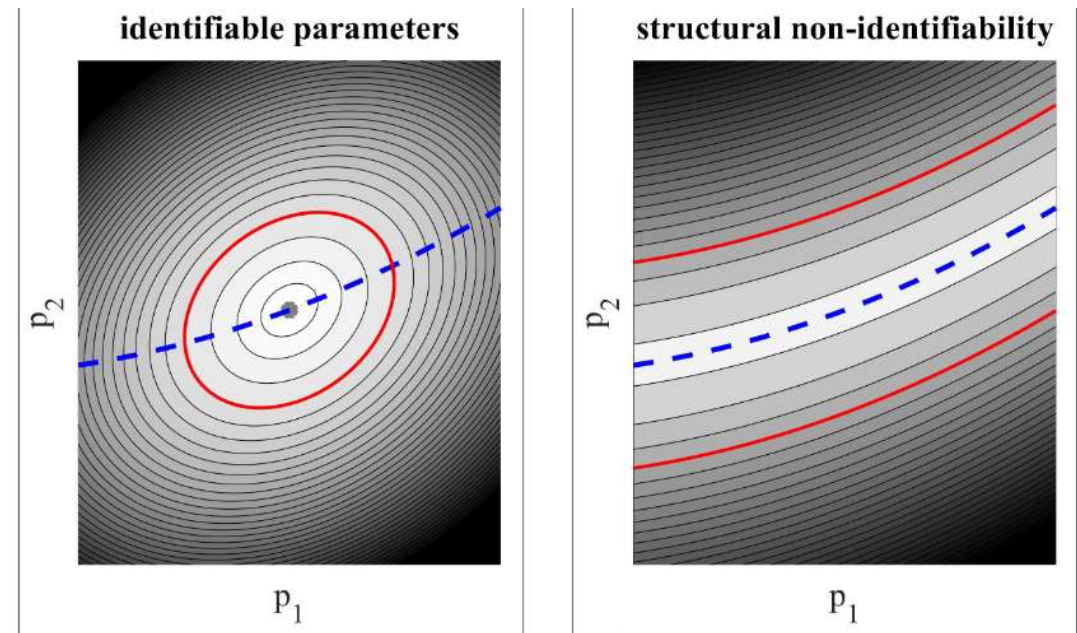

Image from: Wieland, F. G., Hauber, A. L., Rosenblatt, M., Tönsing, C., & Timmer, J. (2021). On structural and practical identifiability. *Current Opinion in Systems Biology*, 25, 60-69.

Bayesian inference: combine all information

- literature
- lab measurements
- experience

+

- model assumptions
- field data

- “updated” knowledge

$p(\theta)$

prior distribution

×

$p(Y_{obs}|\theta)$

likelihood function
(the same as for MLE)

\propto

$p(\theta|Y_{obs})$

posterior distribution

Bayesian inference

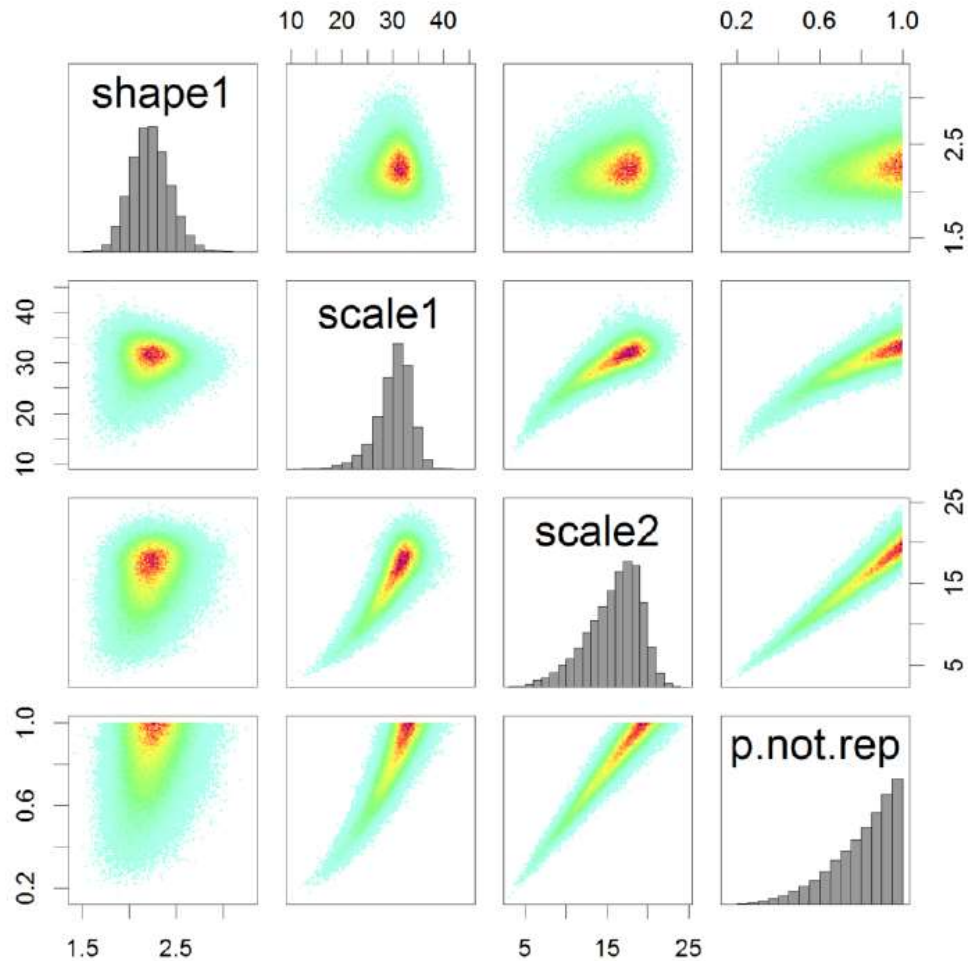

- A principled approach to combine:
 - i. Prior information  
 - ii. Data 
- Based on subjective probability interpretation
- More intuitive interpretation of uncertainty intervals
- Computationally demanding (need to run the model >1000 times)
- Typically used with Monte Carlo Markov Chain (MCMC) sampling

$$p(\theta|Y_{obs}) = \frac{p(Y_{obs}|\theta)p(\theta)}{p(Y_{obs})} = \frac{p(Y_{obs}|\theta)p(\theta)}{\int p(Y_{obs}|\theta')p(\theta')d\theta'}$$

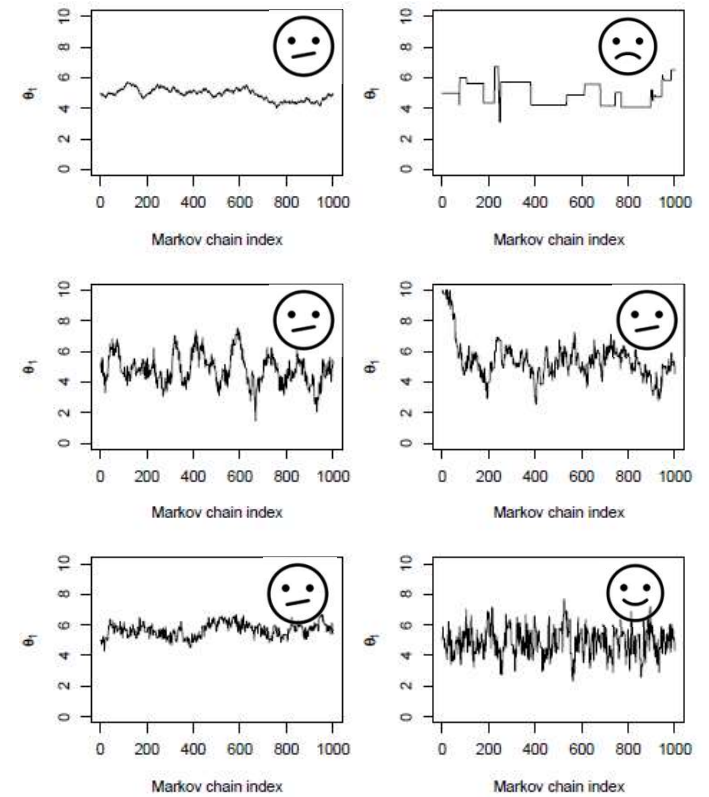

This is often difficult!

Monte Carlo Markov Chain sampling

One- and two-dimensional marginal of the posterior distribution

*Diagnostic of MCMC chains.
Tuning is important!*

Multivariate Random Variables

Joint probability: $p(x, y)$

Marginal probability: $p(x) = \int p(x, y) dy$

Conditional probability: $p(x | y) = \frac{p(x, y)}{p(y)}$

Combining above definitions gives Bayes Theorem:

$$p(x | y) = \frac{p(x, y)}{p(y)} = \frac{p(x) p(y | x)}{p(y)} = \frac{p(x) p(y | x)}{\int p(x') p(y | x') dx'}$$

Demo

Bayesian Regression

Summary

Model uncertainties

1. Input uncertainty
2. Parameter uncertainty
3. Model structure uncertainty
4. Output (measurement) uncertainty
5. (Scenario uncertainty)

Stop worrying and use
Monte Carlo error propagation!

Uncertainties can be described by
probability distributions

Parameter values

Information sources:

i) literature

ii) laboratory experiments

iii) field measurements

Model calibration:

**ChatGPT, please write a short guided meditation
on Bayesian inference and uncertainty**

Take a deep breath and close your eyes.

Visualize yourself in a calm, peaceful environment, surrounded by a soothing aura of uncertainty.

Imagine you have a set of prior beliefs about the world, represented as probabilities.

With each new piece of data you receive, your beliefs are updated to better reflect reality. This process is Bayesian inference.

Embrace the uncertainty that comes with not knowing everything, and trust the power of your beliefs to adapt and evolve with new information.

Remember, the true value of a belief is not in being correct, but in allowing you to make the best decisions given the information you have.

Take another deep breath, and when you're ready, open your eyes, feeling refreshed and empowered by your understanding of Bayesian inference and uncertainty.

Bayesian Inference

$$\underbrace{p(\theta \mid Y_{\text{obs}})}_{\text{Posterior distribution}} \propto \underbrace{p_M(Y_{\text{obs}} \mid x, \theta)}_{\text{Likelihood function}} \underbrace{p(\theta)}_{\text{Prior distribution}}$$

- The **likelihood** function is the same as for MLE
- **Prior** describes our “knowledge” about the parameters *before* calibration
- **Posterior** describes our “knowledge” about the parameters *after* calibration
- Bayesian inferences is based on subjective probability interpretation
- Parameter uncertainty is completely described
